THIRTEEN varieties of soybeans have been registered for introduction in 1955.

Dortchsoy 67 originated as a selection from the progenies of a cross between the Dunfield and Arksoy 2913 varieties in a cooperative program between the Delta Branch, Mississippi Agricultural Experiment Station and the U. S. Regional Soybean Laboratory. The variety is characterized by determinate growth habit, pronounced side branching, dense spreading foliage with exception of late-season weed control. Additional information on Dortchsoy 67 (Reg. No. 67) has been published.

Dorman originated as an F, plant selection from the progeny of a cross between the Dunfield and Arksoy 2913 varieties in a cooperative program between the Delta Branch, Mississippi Agricultural Experiment Station and the U. S. Regional Soybean Laboratory. The variety is characterized by determinate growth habit, moderate height, prolific side branching, dense spreading foliage with exception of late-season weed control. Additional information on Dorman has been increased and released cooperatively in the Delta area. Dorman has given relatively comparable to those of S-100, Dorman has given relatively greater ground cover which results in more effective late-season weed control. Additional information on Dorman has been released cooperatively in the Delta area. Dorman has given relatively greater ground cover which results in more effective late-season weed control.

Oil content of Dortchsoy 67 is higher than S-100 (table I), the variety extends slightly southward. Dortchsoy 67 has been the predominant variety.
