Registration of Crop Cultivars

REGISTRATION OF CM 72 BARLEY1
(Reg. No. 150)

C. W. Schaller, J. P. Prato, M. J. Smith, and C. I. Chim2

'CM 72' barley (Hordeum vulgare L.), CI 15553, was developed at the Univ. of California, Davis. It is a composite of 240 F₄ generation lines selected from the cross, 'California Mariout' × CI 1179/2 × California Mariout/3/CM 67. Final selection of the individual lines was made in 1972. The experimental number for CM 72 during development was UCD 191.

CM 72 is the second backcross-derived strain released for production in California which has been derived from the original California Mariout cultivar. It differs from the earlier release, CM 67, by the addition of the M₁₄ gene for resistance to powdery mildew, transferred from CI 1179. Cumulative additions to the recurrent parent, California Mariout, include resistance to powdery mildew (Erysiphe graminis D. Ell. f. sp. hordei Em. Marchal), tolerance to the barley yellow dwarf virus (Yd2 gene from CI 2376), tolerance to certain physiologic races of scald, Rynchosporium secalis (associated with the transfer of tolerance to the BYDV), and a white aleurome.

CM 72 is an early maturing, six-rowed, rough awned, spring-type feed barley with short straw and medium-dense spikes. The kernels are large, with white aleurome and long-haired rachilla. Except for kernel color and disease reaction, it is similar to California Mariout in all other characteristics and the only known difference from CM 67 is its reaction to powdery mildew.

In 22 location-year comparisons throughout the major barley producing areas of California, CM 72 yielded 5% more than CM 67, with a maximum difference of 19% at one location. This differential is attributed to the effects of powdery mildew on yield. In 12 of these tests, in which the recurrent parent, California Mariout, was included, yield increase of 32 and 35% over California Mariout were measured for CM 67 and CM 72, respectively; the major yield differential being attributed to tolerance of the latter cultivars to the BYDV and the slight differential between them (3%) to their differential mildew reaction.

CM 72 was released by the Univ. of California, Davis, in 1974. Its area of adaptation is similar to that of CM 67 and the recurrent parent, California Mariout, and is recommended for all areas where these varieties have been grown successfully.

Breeder seed will be maintained by the Dep. of Agronomy and Range Science, Univ. of California, Davis.

Garfield (Reg. No. 9) (WA110-9) originated as a plant selection made in 1970 from PI 244104, a small-seeded line. The selection was evaluated for resistance to the pea root rot complex present in each state, which includes Fusarium root rot caused by F. oxysporum f. sp. pisi (F. R. Jones) Snyd. & Hans., Pythium root rot caused by Pythium ultimum Trow., and Rhizoctonia root rot causing by Rhizoctonia solani Kuehn. Preliminary yield tests were made in 1972, and subsequent crop trials were conducted at four locations in 1973 and 1974, and five locations in 1975. In the final 3 years of testing, Garfield showed a yield advantage of 14% over the highest-yielding checks. Garfield is resistant to Fusarium wilt (F. oxysporum f. sp. pisi (Linf.) Snyd. & Hans.) race 1, a potential disease of peas in the Palouse region, but it is susceptible to races 2 and 5.

Garfield is a field pea type that grows an average of 6 cm taller than Alaska. The vine habit of Garfield is indeterminate, nonbranching with straight internodes. Leaflets are broad, and slightly marbled with medium wax. The leaflet pairs. The stipules are normal, nonclasping, and marbled. The flowers are white and usually borne singly or more than a week later than Alaska. Garfield did not differ from Alaska in resistance to powdery mildew. (Erysiphe pisi) or seed bleach, or mechanical damage.

Tracer (Reg. No. 10) (WA1582) originated as a plant selection taken in 1964 from a mixed seed lot of Alaska originating from Canners Seed Corporation of Lewisville, Idaho. Preliminary tests for yield and resistance to the pea root rot complex were conducted in 1972. Subsequent crop trials were conducted at four locations in 1973 and 1974 and three locations in 1975. In those tests, Tracer had a yield advantage of 46% over the small-sieve (6.5 mm in diameter) 'Lilaska'.

Tracer is a field pea type that grows an average of 6 cm taller than Lilaska. The vine habit is indeterminate, nonbranching with straight internodes. Leaflets are broad, with medium wax and slight marbling. The leaflet pairs. The stipules are nonclasping, and marbled. The flowers are white and usually borne in clusters on the peduncles. Pods are straight, bluish green, round, and smooth with green cotyledons, and they weigh 22 g/100 seeds. Garfield flowers in the 14th node compared with the 12th node for Alaska. Because of the difference in flowering node and the tolerance to pea root rot, Garfield matures about 1 week later than Alaska. Garfield did not differ from Alaska in resistance to powdery mildew, (Erysiphe pisi) or seed bleach, or mechanical damage.

Breeder and foundation seed will be maintained by the Dept. of Agronomy and Range Science, Univ. of California, Davis, CA 95616.

REGISTRATION OF GARFIELD AND TRACER DRY PEAS1
(Reg. No. 9 and 10)

F. J. Muchlbauser, V. E. Wilson, J. M. Kraft, and R. E. Witters2

1 Registered by the Crop Sci. Soc. of Am. Accepted 1 Dec. 1976.
2 Professor, Dep. of Agronomy and Range Science; extension agronomist, Cooperative Extension; staff research associate; and staff research associate, emeritus, respectively, Univ. of California, Davis, CA 95616.
