REGISTRATION OF CROP GERMPLASMS

which has consistently been the highest yielding synthetic in previous tests (3,4), but NDSBF had lower ear moisture (2.63 percentage points) at harvest than NDSAB. NDSBF averaged almost 70% higher grain yield, and had lower ear moisture, stalk lodging, and root lodging percentages than the mid-parental values for NDSB and NDSF in 1984 tests averaged over four locations in North Dakota. NDSBF is AES100 maturity.

Breeder seedstocks are maintained by the North Dakota Agric. Exp. Stn. and can be obtained in germplasm quantities (200 kernels) from H.Z. Cross, Agronomy Dep., North Dakota State Univ., Fargo, ND 58105.

REGISTRATION OF THREE OAT GERMPLASM LINES RESISTANT TO THE CROWN RUST FUNGUS

OAT (Avena sativa L.) germplasm lines H632-518, H590-293, and H639-662 (Reg. no. GP-36, GP-37, and GP 38) were developed by USDA-ARS, in cooperation with the Iowa Agriculture and Home Economics Experiment Station and released in 1986. The primary reason for release is that these lines, even though lacking seedling resistance, are relatively resistant to crown rust (caused by Puccinia coronata Cda. var. avenae Fraser Led.) in the field. The field resistance was derived from strains of A. sterilis L. collected in Israel (1). Such field resistance usually is durable over time, and the three lines give adequate protection under conditions of natural infection. They will be useful as parents to produce cultivars with durable resistance to crown rust.

The three A. sterilis parental lines were all susceptible to common races of crown rust as seedlings in the greenhouse. They showed field resistance, however, when compared with susceptible cultivated oats (2). ‘Clinton’ was the female and recurrent parent in all crosses. H632-518, H590-293, and H639-662 are available upon request from K.J. Frey, Dep. of Agronomy, Iowa State University, Ames, IA. Project no. 2447. Registration by the Crop Sci. Soc. 27:368-369 (1987).

REGISTRATION OF LESAF 175 SAFFLOWER GERMPLASM LINE

LESAF 175 (Reg. no. GP-32) germplasm line is rust resistant, white flowered, moderately early maturing line resulting from mass selection in the greenhouse. It was selected from the cross Clinton × A. sterilis PI 309561. Observed visually, it usually appeared moderately susceptible to the crown rust fungus in the field. In 5 yr of testing under rust-free conditions, H639-293 yielded 98% as much as Clinton, but with severe crown rust infection, yields of Clinton were reduced 65%, whereas yields of H639-293 were reduced only 25%.

Published March, 1987

References and Notes

The elite germplasm line PCA has moderate seedling resistance and high foliage resistance to rust, caused by Puccinia coronata Cda. This resistance was derived from a parent that carried the dominant allele of the A resistance gene in a plant that segregated from the cross Clinton × A. sterilis PI 309561. Observed visually, it usually appeared moderately susceptible to the crown rust fungus in the field. In 5 yr of testing under rust-free conditions, H639-293 yielded 98% as much as Clinton, but with severe crown rust infection, yields of Clinton were reduced 65%, whereas yields of H639-293 were reduced only 25%.

H639-662 (PI 501532) (GP-38) was derived from F4, plant that segregated from the cross Clinton × A. sterilis PI 309561. Observed visually, it usually appeared moderately susceptible to the crown rust fungus in the field. In 5 yr of testing under rust-free conditions, H639-293 yielded 98% as much as Clinton, but with severe crown rust infection, yields of Clinton were reduced 65%, whereas yields of H639-293 were reduced only 25%.
